

UFW

During my training, we used UFW (Uncomplicated Firewall) on a Linux machine to filter inbound and outbound traffic, specifically to block access to explicit content as part of a practical lab on network controls and policy enforcement.

The exercise taught me how simple, well-configured firewall rules can enforce organizational policies, reduce exposure to risky sites, and improve overall network hygiene. More importantly, it reinforced the idea that security controls aren't just technical. They protect people and maintain trust in digital environments.

We conducted this work in a controlled lab environment, documented our tests, and discussed safe deployment practices for live networks (policy, monitoring, and user awareness). Hands-on tasks like this make abstract security concepts tangible and directly applicable to real-world operations.
