

Linux Basics - Creating Users and File Permissions

One thing I've learned in cybersecurity is that not everyone should have access to everything, and that simple idea can save an entire organization.

During my six-month intensive training in Linux system administration, I worked on a project that brought this concept to life through the Principle of Least Privilege.

I created users and groups, managed permissions, and ensured only authorized individuals could access specific files, even within the same team. Some permissions were deliberately removed to strengthen control and minimize risks.

That experience taught me that cybersecurity isn't just about tools; it's about discipline and structure.

Proper access control reduces insider threats, builds trust, and protects data.

As I continue to grow in cybersecurity and system administration, I'm committed to creating secure, well managed environments where safety and efficiency work hand in hand.
